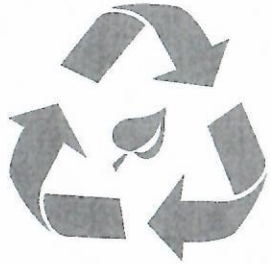
Why Wingdig?

- A successful home compost bin - free of flies, unpleasant odour and vermin (including nesting mice and rats) is a result of thorough and frequent turning and aerating of the compost pile.
- The wingdigger is specially designed to get right down to the bottom of your compost pile particularly in "cone" type backyard bins. It easily lifts and mixes the more decomposed bottom layers with newer compost. Simply plunge it in and out several times.
- The act of wingdigging up the older compost aerates the pile and mixes compost-causing bacteria throughout, speeding up the process.
- Aeration of the compost pile is important because it allows the flow of moisture through the pile. More air also reduces odour. And if you reduce odour, flies and vermin will not be attracted to the pile. Aeration also results in garden compost becoming rich loam in just one season.

More Composting Tips:

- An active compost heap should feel like a wrung out sponge. Cover the pile to keep excess moisture out.
- Never put meat, bread or dairy products into your compost bin.
- Filling your compost bin with a variety of organic waste e.g. grass clippings, leaves, kitchen waste and an occasional scoop of dirt is an ideal mixture.
- Compost starter soils are also available to promote even faster composting.



And Most Important...Encourage Mother Nature and Wingdig Weekly!
