

Helpful Hints when using the Grout Grabber, #75009Q

To remove grout, always approach the joint at a low speed and cut into the joint to the desired depth. Once at the desired depth, increase the speed of the saw and pull backwards. Note: Never use the saw at full speed.

- Because all saws are different, performance will vary when using the variable speed control. Practice first on a non-visible area to find the length of stroke that is compatible with the grout joint
- Start by using one blade in order to become accustomed with power of the tool and the stroke of the blade. It will also help to test the width of the stroke to determine how many blades are required for your grout joint.
- Be especially careful at grout joint intersections to prevent chipping of tile edges
- A second pass may be necessary to achieve the desired outcome
- Let the adapter do the work – excess pressure limits the blade life
- Rotate the outer carbide grit blades for even wear and increased blade life
- For thicker grout joints, add QEP Grout Saw Replacement Blades, #75011Q

Note: After use, allow blades to cool before changing or rotating
